

Lecture 4: Dimensionality Reduction

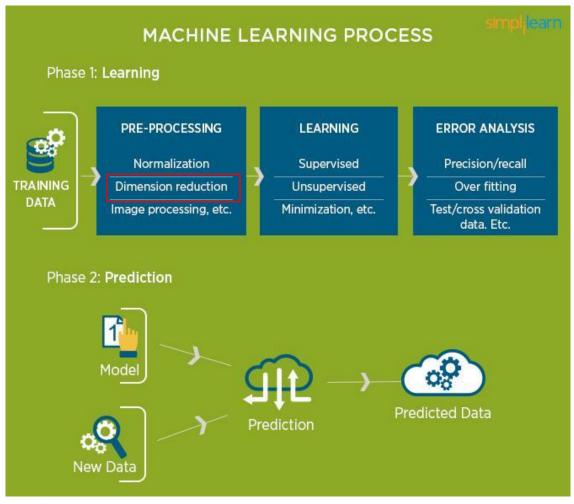

Pilsung Kang
School of Industrial Management Engineering
Korea University

AGENDA

| 01 | Dimensionality Reduction |
|----|----------------------------|
| 02 | Variable Selection Methods |
| 03 | Shrinkage Methods |
| 04 | R Exercise |

Data Analytics Process

Process of Business Analytics with Machine Learning

High-dimensional Data

Examples of high dimensional data

Document classification:

Billions of documents x Thousands/ Millions of words/bigrams matrix

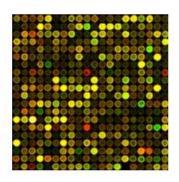

Recommendation systems:

480,189 users x 17,770 movies matrix

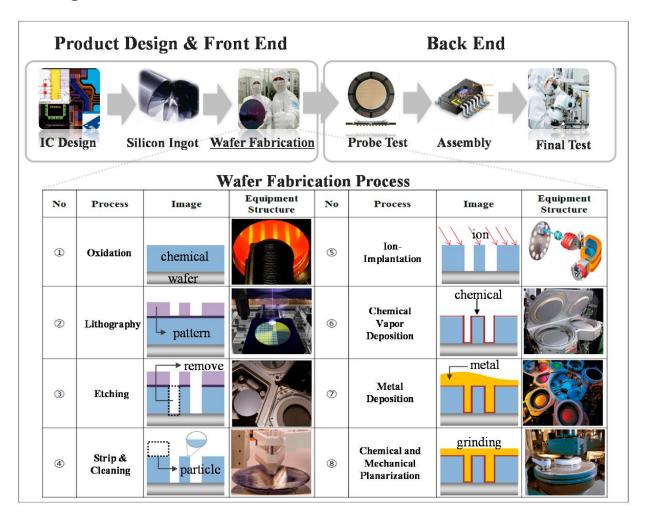

Clustering gene expression profiles:

10,000 genes x 1,000 conditions

High-dimensional Data

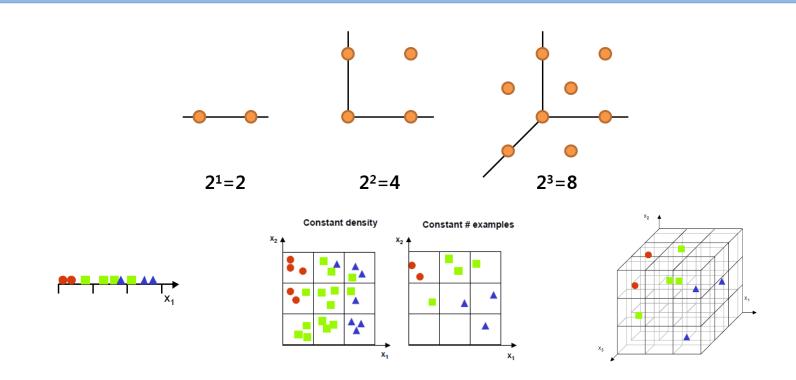

Examples of high dimensional data

Park, S. H., Kim, S., & Baek, J. G. (2018). Kernel-Density-Based Particle Defect Management for Semiconductor Manufacturing Facilities. Applied Sciences, 8(2), 224.

- Curse of dimensionality
 - √ The number of instances increases exponentially to achieve the same explanation
 ability when the number of variables increases

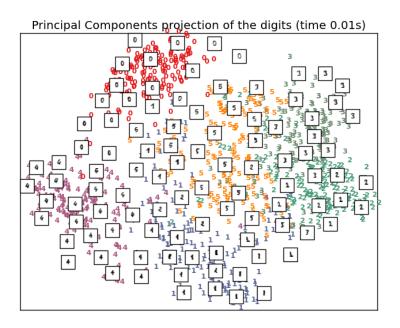

"If there are various logical ways to explain a certain phenomenon, the simplest is the best" - Occam's Razor

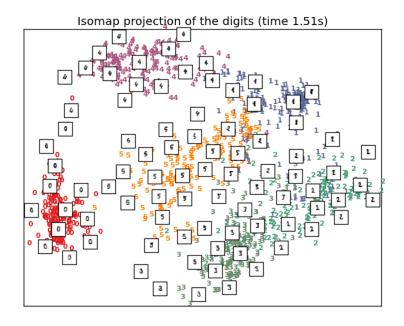

- Curse of dimensionality
 - ✓ Sometimes, an intrinsic dimension is relatively low compared to the original dimension.
 - Ex: handwritten digits in a 16 by 16 pixel (256 dimensions)

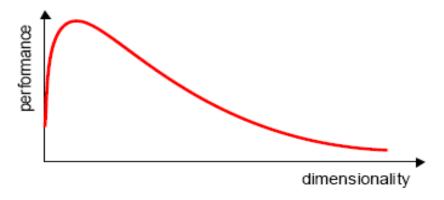

- Curse of dimensionality
 - ✓ Sometimes, an intrinsic dimension is relatively low compared to the original dimension.
 - Ex: handwritten digits in a 16 by 16 pixel (256 dimensions)
 - Reduced to two dimensions by PCA and ISOMAP

- Curse of dimensionality
 - ✓ Problems caused by high-dimensionality
 - Increase the probability of having noise in data \rightarrow degenerate the prediction performance
 - Increase computational burden for training/applying prediction models
 - Require more number of examples to secure generalization ability of prediction model
 - ✓ To resolve the curse of dimensionality
 - Utilize domain knowledge
 - Use a regularization term in objective function
 - Employ a quantitative reduction technique

Backgrounds

- ✓ Theoretically, model performance improves when the number of variables increases
 (Under variable independence condition)
- ✓ In reality, model performance degenerates due to variable dependence, existence of noise, etc.

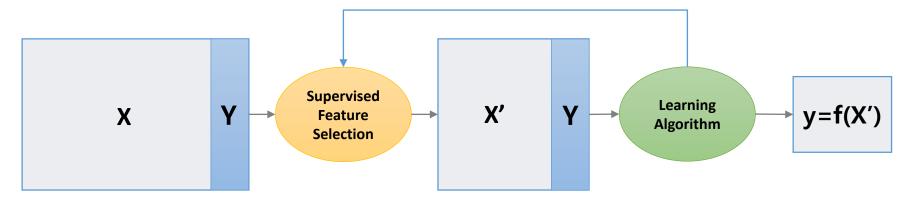

Purpose

✓ Identify a subset of variables that best fit the model

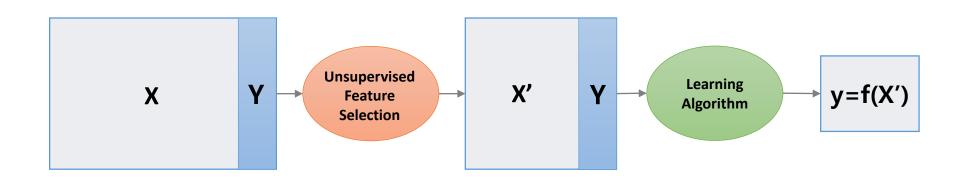

Effect

- ✓ Remove correlations between variables
- √ Simplified post-processing
- √ Remove redundant or unnecessary variables while keeping relevant information
- ✓ Visualization can be possible

- Supervised vs. Unsupervised Dimensionality Reduction
 - √ Supervised dimensionality reduction
 - Use data mining models to verify the reduced dimensions
 - Dimensionality reduction results can be different according to the data mining algorithms employed

- Supervised vs. Unsupervised Dimensionality Reduction
 - ✓ Unsupervised dimensionality reduction
 - Find a set of coordinate systems in a lower dimension that preserve the information (e.g., variance, distance, etc.) in the original input space as much as possible
 - Do not use data mining models during the process
 - Dimensionality reduction results are identical if the data and method is same

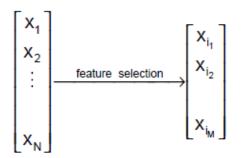

Dimensionality reduction techniques

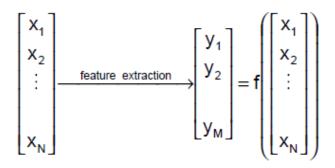

√ Variable/feature selection

- Select a subset of variables from the original variable set
- Filter Variable selection and model training are independent
- Wrapper Variable selection is done to optimizes the result of the considered data mining model

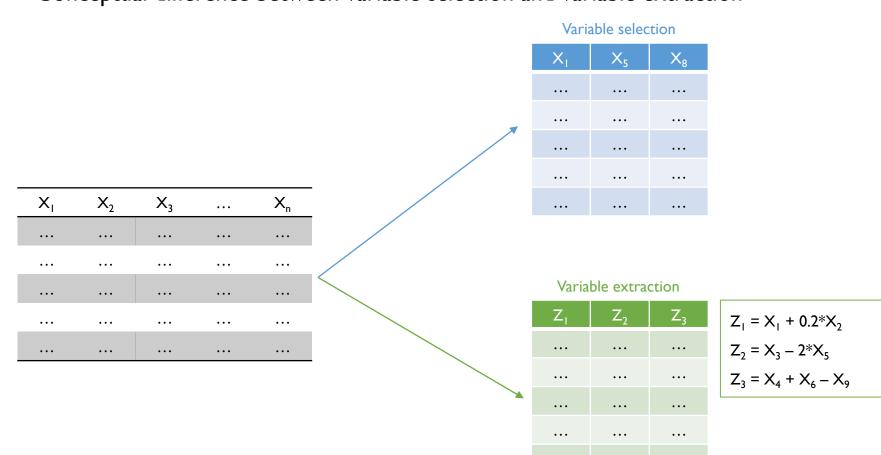

√ Variable/feature extraction

- Extract a new smaller set of variables that preserve the characteristics of the original data
- Performance metric that is independent from data mining models is used

- Selection vs. Extraction
 - ✓ Conceptual difference between variable selection and variable extraction

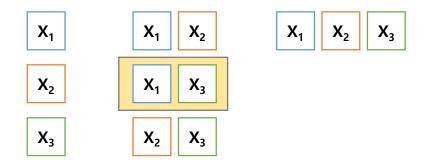

AGENDA

| 01 | Dimensionality Reduction |
|----|----------------------------|
| 02 | Variable Selection Methods |
| 03 | Shrinkage Methods |
| 04 | R Exercise |

Exhaustive Search

- Exhaustive search
 - √ Search all possible combinations

 - A total of 7 possible subsets are tested

- ✓ Performance criteria for variable selection
 - Akaike Information Criteria (AIC), Bayesian Information Criteria (BIC), Adjusted R²,
 Mallow's C_p, etc.

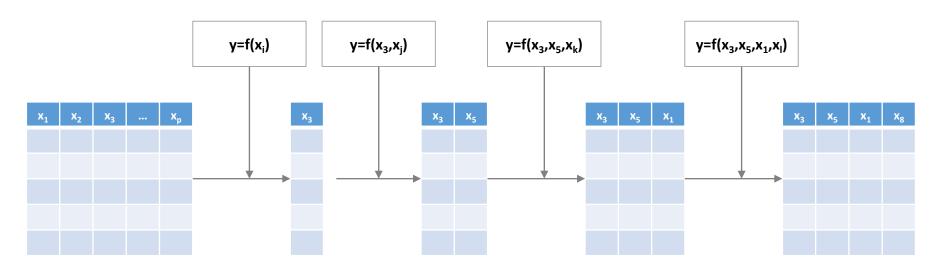

Exhaustive Search

- Exhaustive search
 - ✓ Assume that we have a computer that can evaluate 10,000 models/second

Forward Selection

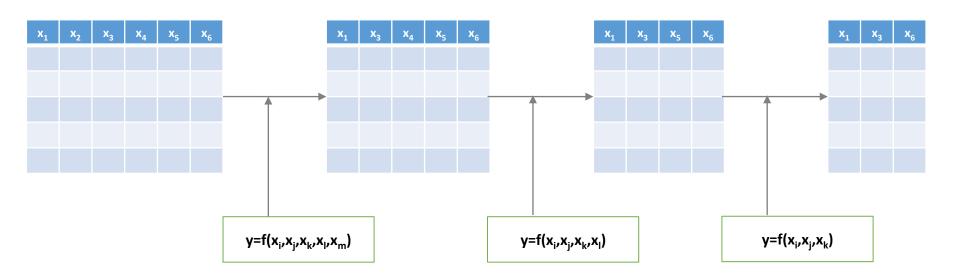

- Forward selection
 - √ From the model with no variable, significant variables are sequentially added
 - ✓ Once the variable is selected, it will never be removed (The number of variables gradually increases)

Backward Elimination

Backward Elimination

- ✓ From the model with all variables, irrelevant variables are sequentially removed.
- ✓ Once a variable is removed, it will never be selected (The number of variables gradually decreases)

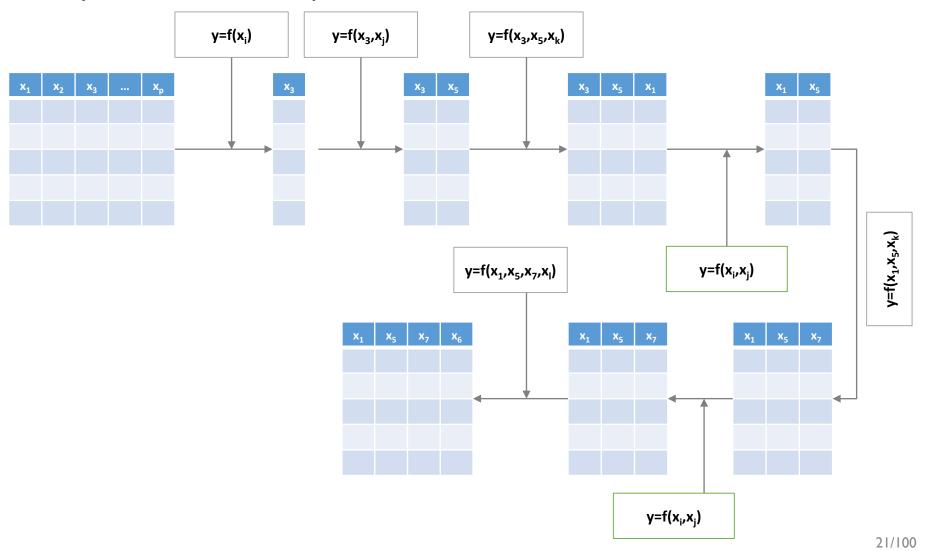

Stepwise Selection

Stepwise Selection

- ✓ From the model with no variable, conduct the forward selection and backward elimination alternately
- ✓ Takes longer time than forward selection/backward elimination, but has more chances
 to find the optimal set of variables
- √ Variables that is either selected/removed can be reconsidered for selection/removal.
- ✓ The number of variables increases in the early period, but it can either increase or
 decrease

Stepwise Selection

Stepwise selection example

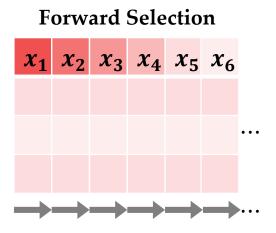

Stepwise Selection

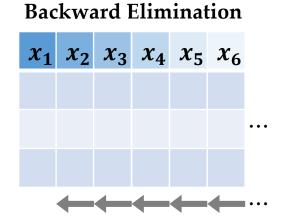

Stepwise Selection

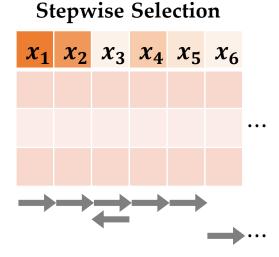

- √ Stepwise selection process
 - Start with model with no predictors.
 - ▶ Add variable with largest *F*-statistic (provided *P* less than some cut-off).
 - ▶ Refit with this variable added. Recompute all *F* statistics for adding one of the remaining variables and add variable with largest *F* statistic.
 - ► At each step after adding a variable try to eliminate any variable not significant at some level (that is, do BACKWARD elimination till that stops).
 - After doing the backwards steps take another FORWARD step.
 - Continue until every remaining variable is significant at cut-off level and every excluded variable is insignificant OR until variable to be added is same as last deleted variable.

Comparison among FS/BE/SS

Illustrative Example

Performance Metrics

- Akaike Information Criteria (AIC)
 - √ Sum of squared error (SSE) with the number of variables as a penalty term

$$AIC = n \cdot ln\left(\frac{SSE}{n}\right) + 2k$$

- Bayesian Information Criteria (BIC)
 - ✓ SSE, number of variables, standard deviation obtained by the model with all variables

$$BIC = n \cdot ln\left(\frac{SSE}{n}\right) + \frac{2(k+2)n\sigma^2}{SSE} - \frac{2n^2\sigma^4}{SSE^2}$$

Performance Metrics

Adjusted R²

✓ Simple R² increases when the number of variable increases

Model 1:
$$y = \beta_0 + \beta_1 x_1 + \ldots + \beta_k x_k + \epsilon$$

Model 2: $y = \beta_0 + \beta_1 x_1 + \ldots + \beta_k x_k + \ldots + \beta_{k+m} x_{k+m} \epsilon$ $R^2(M2) \ge R^2(M1)$

 \checkmark Use the adjusted R² that account for the number of variables (k)

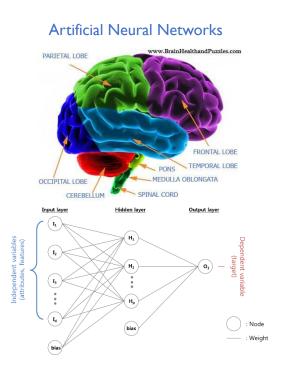

Adjusted
$$R^2 = 1 - \left(\frac{n-1}{n-k-1}\right)(1-R^2) = 1 - \frac{n-1}{n-k-1}\frac{SSE}{SST}$$

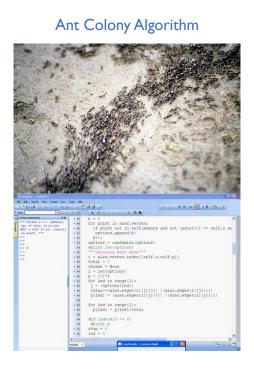

- Limitations of the previous variable selection methods
 - ✓ Exhaustive search: guarantee the optimal subset, but takes too long time (practically impossible for many tasks)
 - ✓ Local search (forward/backward/stepwise): efficient search but the search space is very limited, which leads to a low probability of finding the optimal solution

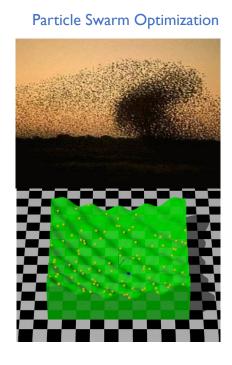

• Idea

√ Improve the performance of local searches with a little additional computational time!

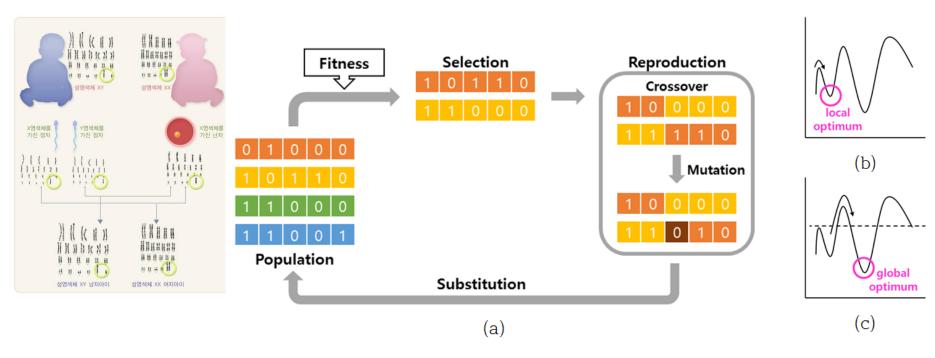

- Meta-Heuristic Approach
 - √ Solve a complex problem by doing trials and errors efficiently
 - ✓ Among the optimization algorithms, many of them mimic the way of a natural system works

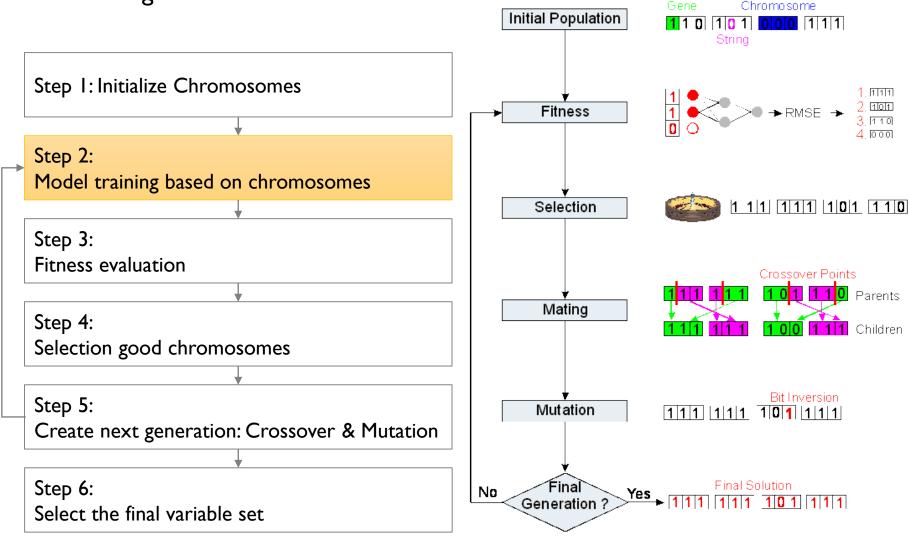

- An Evolutionary Algorithm that mimics the Reproduction of Creatures
 - √ Find a superior solutions and preserve by repeating the reproduction process
 - Selection: Select a superior solution to improve the quality
 - Crossover: Search various alternatives based on the current solutions
 - Mutation: Give a chance to escape the local optima

Genetic Algorithm for Feature Selection

GA Step 1: Initialization

Encoding Chromosomes

- ✓ Genetic algorithm can be used not only for variable selection, but for a wide range of optimization problems
- ✓ Encoding scheme can be different for different tasks
- ✓ Binary encoding is commonly used for variable selection

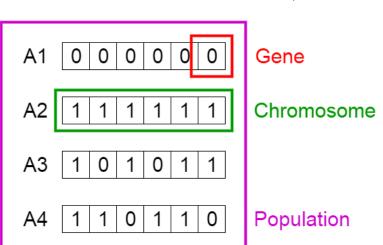

| x ₁ x ₂ x ₃ x ₄ x ₅ x ₆ x ₇ x ₈ x _d | Chromosome | | | | Gene | | | | |
|--|-----------------------|----------------|---|-----------------------|-----------------------|---|-----------------------|---|--------------------|
| | x ₁ | X ₂ | | X ₄ | X ₅ | | x ₇ | | x _d |
| | () | 0 | 0 | 1 | 0 | 1 | 1 | 0 | 1 |

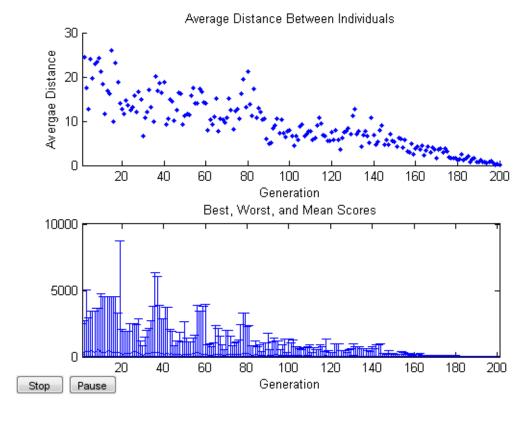

I: Use the corresponding variable in the modeling

^{0:} Do not use the variable

GA Step 1: Initialization

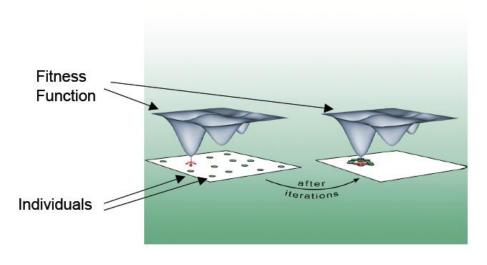

- Parameter Initialization
 - √ The number of chromosome (population)
 - √ Fitness function
 - √ Crossover mechanism
 - ✓ The rate of mutation
 - ✓ Stopping criteria
 - minimum fitness improvement
 - maximum iterations, etc.

GA Step 3: Fitness Evaluation

- Fitness Function
 - ✓ A criterion that determines which chromosomes are better than others
 - ✓ In general, the higher the fitness value, the better the chromosomes
 - ✓ Common criteria that are embedded in the fitness function
 - If two chromosomes have the same fitness value, the one with fewer variables is preferred
 - If two chromosomes use the same number of variables, the one with higher predictive performance is preferred
 - √ In case of multiple linear regression
 - Adjusted R2
 - Akaike information criterion (AIC)
 - Bayesian information criterion (BIC)

GA Step 4: Selection

Selection

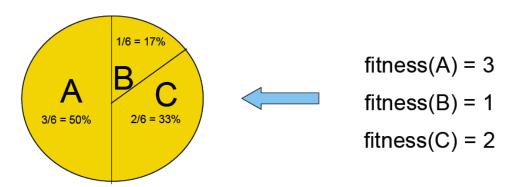

✓ Select superior chromosomes in the current population to reproduce the population of the next generation

✓ Deterministic selection

- Select only top N% of chromosomes
- Bottom (100-N)% chromosomes are never selected

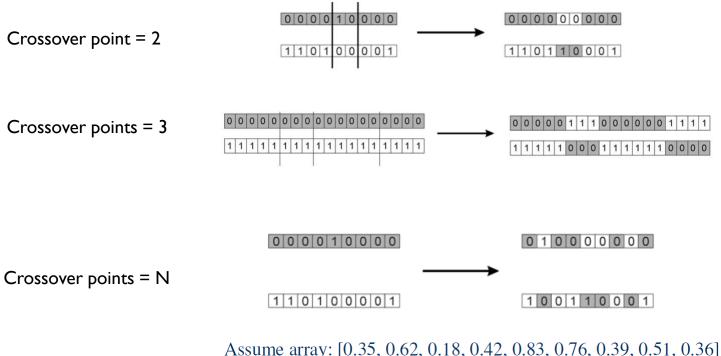

✓ Probabilistic selection

- Use the fitness value of each chromosome as the selection weight
- All chromosomes can be selected with different probabilities

GA Step 5: Crossover & Mutation

- Crossover (Reproduction)
 - ✓ Two child chromosomes are produced from two parent chromosomes
 - ✓ The number of crossover points can vary from I to n (total number of genes)

GA Step 5: Crossover & Mutation

Mutation

- ✓ Genetic operator used to maintain diversity from one generation of a population of chromosomes to the next
- ✓ Alters one or more gene values in a chromosome from its initial state, which result in
 entirely new gene values being added to the gene pool
- ✓ By mutation, the current solution can have a chance to escape from the local optima
- \checkmark A too mutation rate can increase the time to converge (0.01 can be a good choice)

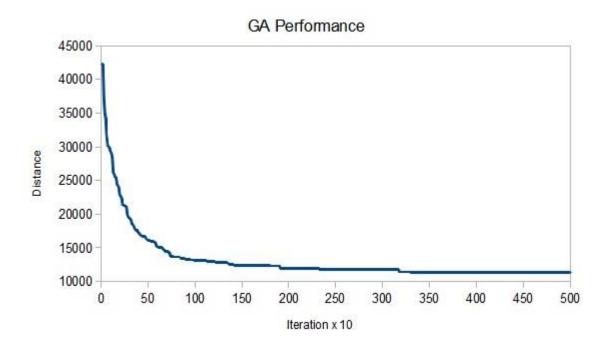

Consider the two original off-springs selected for mutation.

Invert the value of the chosen gene as 0 to 1 and 1 to 0

The Mutated Off-spring produced are:

GA Step 5: Find the Best Solution

- Find the best variable subset
 - ✓ Select the chromosome with the highest fitness value after the stopping criteria are satisfied.
 - ✓ Generally, significant fitness improvement occurs in the early stages, which becomes marginal after some generations

AGENDA

| 01 | Dimensionality Reduction |
|----|----------------------------|
| 02 | Variable Selection Methods |
| 03 | Shrinkage Methods |
| 04 | R Exercise |

Revisit MLR

- Multiple Linear Regression
 - √ Formulation

$$\hat{y} = \hat{\beta_0} + \hat{\beta_1} x_1 + \hat{\beta_2} x_2 \cdots + \hat{\beta_d} x_d$$

√ Objective function (should be minimized)

$$\frac{1}{2} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 = \frac{1}{2} \sum_{i=1}^{n} \left(y_i - \sum_{j=0}^{d} \hat{\beta}_j x_{ij} \right)^2$$

Revisit Logistic Regression

- Logistic Regression
 - √ Formulation

$$log(Odds) = log\left(\frac{p}{1-p}\right) = \hat{\beta_0} + \hat{\beta_1}x_1 + \hat{\beta_2}x_2 + \dots + \hat{\beta_d}x_d$$

√ Objective function (should be minimized)

$$-\sum_{i=1}^{n} \left(y_i \log \left(\frac{1}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)} \right) + (1 - y_i) \log \left(\frac{\exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)} \right) \right)$$

Ridge Regression

Ridge Linear Regression

$$\frac{1}{2} \sum_{i=1}^{n} \left(y_i - \sum_{j=0}^{d} \hat{\beta}_j x_{ij} \right)^2 + \lambda \sum_{j=1}^{d} \hat{\beta}_j^2$$

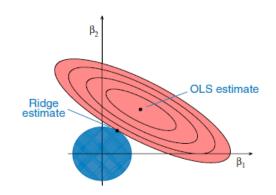

Ridge Logistic Regression

$$-\sum_{i=1}^{n} \left(y_i \log \left(\frac{1}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)} \right) + (1 - y_i) \log \left(\frac{\exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)} \right) \right) + \lambda \sum_{j=1}^{d} \hat{\beta}_j^2$$

Ridge Regression

- Ridge (Logistic) Regression
 - √ Add L₂ nom penalty for the objective function

$$\lambda \sum_{j=1}^{d} \hat{\beta}_j^2$$

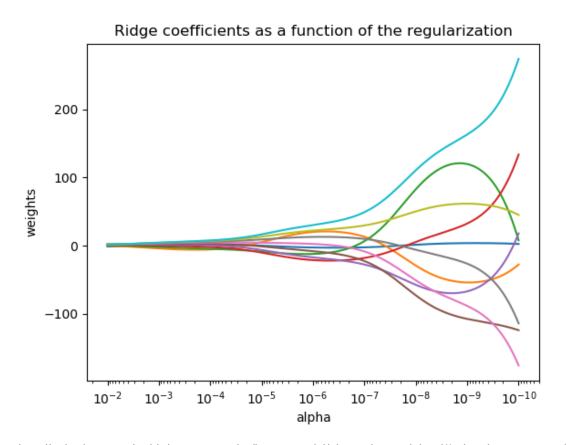

✓ Properties

- If two models have the same performance, smaller regression coefficients are preferred
- Regression coefficients can be very small, but hard to make them exactly 0 → not for variable selection
- Work well when input variables have high correlations

Ridge Regression

- Ridge (Logistic) Regression
 - \checkmark Example of estimated regression coefficients according to different λ

 $http://scikit-learn.org/stable/auto_examples/linear_model/plot_ridge_path.html\#sphx-glr-auto-examples-linear-model-plot-ridge-path-py$

- LASSO: Least Absolute **Shrinkage** and **Selection** Operator
 - ✓ Multiple Linear Regression

$$\frac{1}{2} \sum_{i=1}^{n} \left(y_i - \sum_{j=0}^{d} \hat{\beta}_j x_{ij} \right)^2 + \lambda \sum_{j=1}^{d} |\hat{\beta}_j|$$

✓ Logistic Regression

$$-\sum_{i=1}^{n} \left(y_i \log \left(\frac{1}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta_j} x_j)} \right) + (1 - y_i) \log \left(\frac{\exp(-\sum_{j=0}^{d} \hat{\beta_j} x_j)}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta_j} x_j)} \right) \right) + \lambda \sum_{j=1}^{d} |\hat{\beta_j}|$$

- LASSO: Least Absolute <u>Shrinkage</u> and <u>Selection</u> Operator
 - \checkmark Ridge gives L₂ norm penalty while LASSO gives L₁ norm penalty
 - \checkmark Can make the coefficients of irrelevant variables $0 \rightarrow$ can do variable selection
 - \checkmark The number of selected variables (variables with non-zero coefficients) vary according to λ

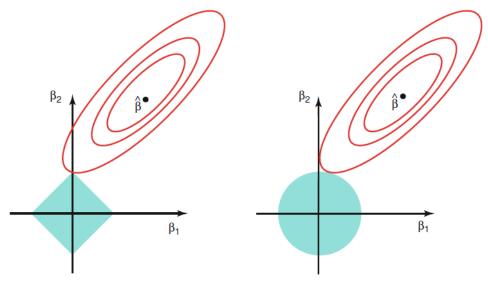

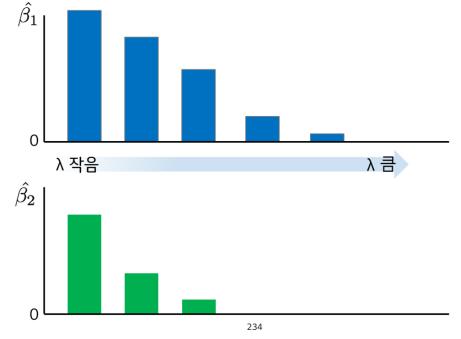

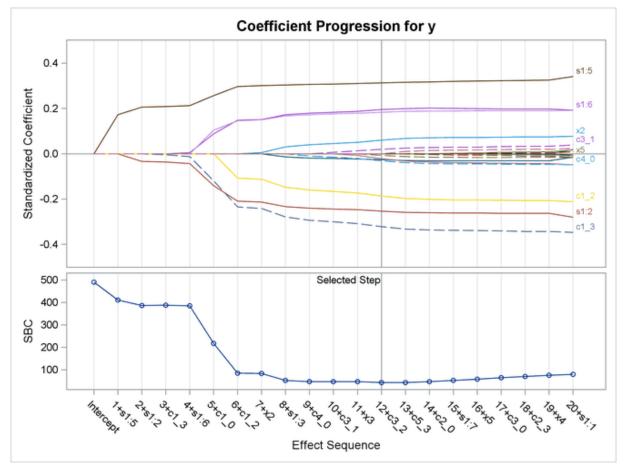

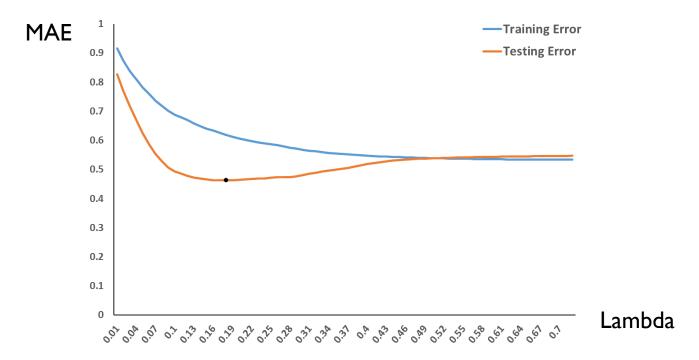

FIGURE 6.7. Contours of the error and constraint functions for the lasso (left) and ridge regression (right). The solid blue areas are the constraint regions, $|\beta_1| + |\beta_2| \le s$ and $\beta_1^2 + \beta_2^2 \le s$, while the red ellipses are the contours of the RSS.

- LASSO: Least Absolute **Shrinkage** and **Selection** Operator
 - \checkmark Example of estimated regression coefficients according to different λ

- LASSO: Least Absolute **Shrinkage** and **Selection** Operator
 - \checkmark determine the best λ with the highest regression performance

✓ Limitation: Both variable selection and regression performance degenerate if variables are highly correlated

Elastic Net

- Elastic Net
 - ✓ Can have advantages of both Ridge (considering correlation between variables) and LASSO (variable selection ability)
 - ✓ Multiple Linear Regression

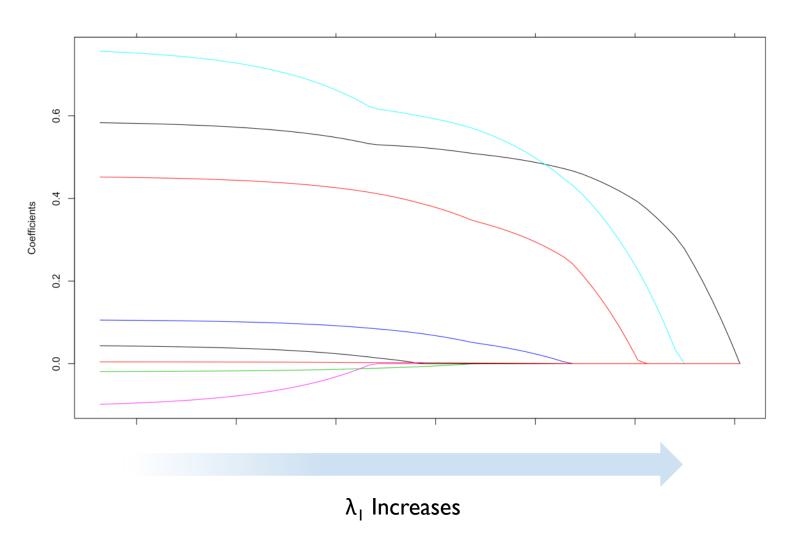

$$\frac{1}{2} \sum_{i=1}^{n} \left(y_i - \sum_{j=0}^{d} \hat{\beta}_j x_{ij} \right)^2 + \lambda_1 \sum_{j=1}^{d} |\hat{\beta}_j| + \lambda_2 \sum_{j=1}^{d} \hat{\beta}_j^2$$

✓ Logistic Regression

$$-\sum_{i=1}^{n} \left(y_i \log \left(\frac{1}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)} \right) + (1 - y_i) \log \left(\frac{\exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)}{1 + \exp(-\sum_{j=0}^{d} \hat{\beta}_j x_j)} \right) \right)$$

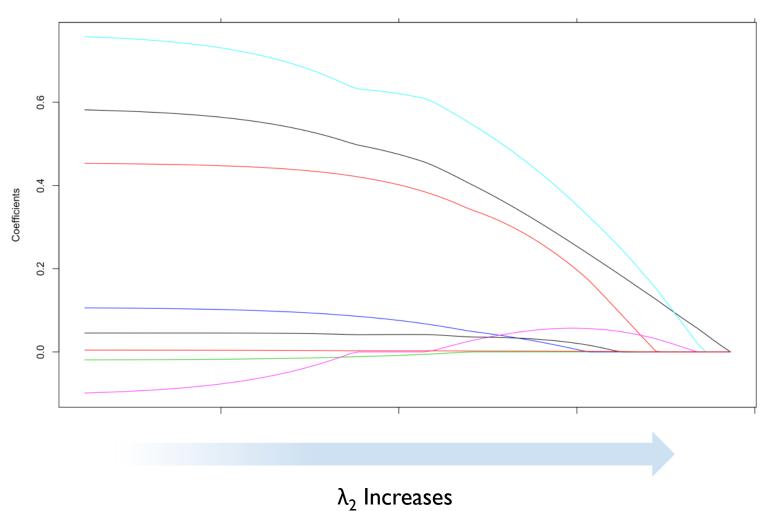

$$+\lambda_1 \sum_{j=1}^{d} |\hat{\beta}_j| + \lambda_2 \sum_{j=1}^{d} \hat{\beta}_j^2$$

Elastic Net

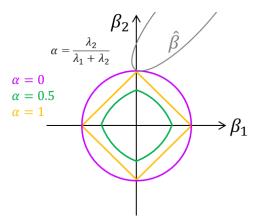

Number of variable decreases

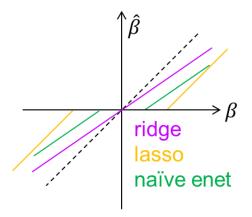

Elastic Net

Little impact on variable selection

- Compare four variable selection methods and three shrinkage methods
 - √ Variable selection: Forward selection, Backward elimination, Stepwise selection, GA
 - √ Shrinkage: Ridge, Lasso, Elasitic Net

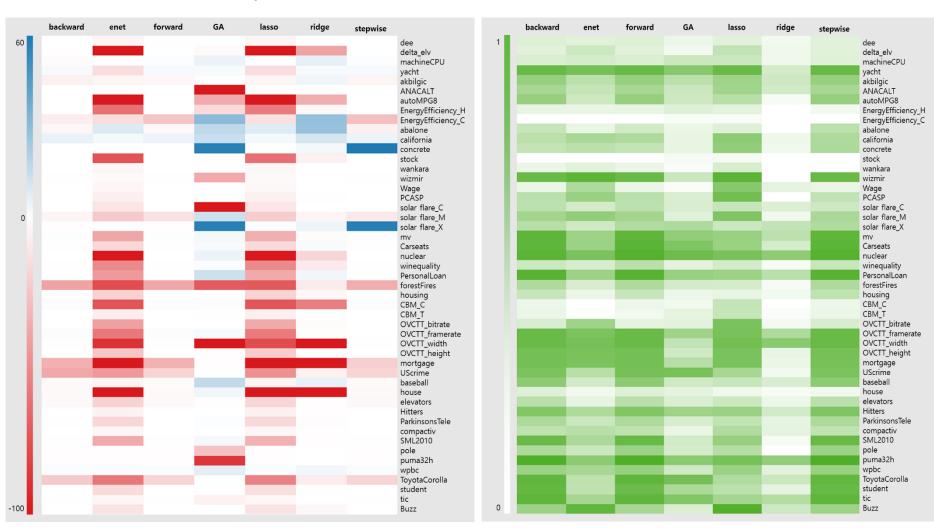

| Ridge | $\hat{\beta} = \min_{\beta} Y - X\beta ^2 + \lambda_1 \beta ^2$ | shrinkage |
|-------------|---|--|
| Lasso | $\hat{\beta} = \min_{\beta} Y - X\beta ^2 + \lambda_2 \beta ^1$ | shrinkage, variable selection |
| Elastic net | $\hat{\beta} = \min_{\beta} Y - X\beta ^2 + \lambda_2 \beta ^1 + \lambda_1 \beta ^2$ | shrinkage, variable selection, grouping effect |

- A total of 14 variables (columns)
- ID, ZIP Code: irrelevant column (remove)
- Personal loan: target variable

R Exercise: Install packages

Install packages and prepare them to be used

```
# Install necessary packages
# glmnet: Ridge, Lasso, Elastic Net Logistic Regression
# GA: genetic algorithm
install.packages("glmnet")
install.packages("GA")
library(glmnet)
library(GA)
```

R Exercise: Performance Evaluation Function

Performance Evaluation Function

```
# Performance Evaluation Function -----
perf eval <- function(cm){</pre>
    # True positive rate: TPR (Recall)
    TPR \leftarrow cm[2,2]/sum(cm[2,1)
    # Precision
    PRE \leftarrow cm[2,2]/sum(cm[,2])
    # True negative rate: TNR
    TNR <- cm[1,1]/sum(cm[1,])
    # Simple Accuracy
    ACC \leftarrow (cm[1,1]+cm[2,2])/sum(cm)
    # Balanced Correction Rate
    BCR <- sqrt(TPR*TNR)
    # F1-Measure
    F1 <- 2*TPR*PRE/(TPR+PRE)
    return(c(TPR, PRE, TNR, ACC, BCR, F1))
}
```

- √ Function name: perf_eval
 - Argument: confusion matrix
 - Outputs: six classification performance metrics

R Exercise: Performance Evaluation Function

Performance Evaluation Function

- ✓ Initialize the performance comparison matrix
- √ A total of 8 logistic regression models are compared
 - All: All variables are used
 - Forward/Backward/Stepwise: Variables selected by Forward Selection, Backward
 Elimination, and Stepwise selection are used
 - GA:Variables selected by genetic algorithm are used
 - Ridge/Lasso/Elastic Net

R Exercise: Data Load and Preprocessing

Data Load and Preprocessing

```
# Load the data & Preprocessing
Ploan <- read.csv("Personal Loan.csv")

Ploan_input <- Ploan[,-c(1,5,10)]
Ploan_input_scaled <- scale(Ploan_input, center = TRUE, scale = TRUE)
Ploan_target <- Ploan$Personal.Loan
Ploan_data_scaled <- data.frame(Ploan_input_scaled, Ploan_target)

trn_idx <- 1:1500
tst_idx <- 1501:2500

Ploan_trn <- Ploan_data_scaled[trn_idx,]
Ploan_tst <- Ploan_data_scaled[tst_idx,]</pre>
```

- ✓ Remove Ist, 5th, and 10th columns from input variables
- ✓ Perform input variable normalization
- ✓ Use the first 1,500 rows for training and the other 1,000 rows for test

Logistic Regression I:All variables

```
# Variable selection method 0: Logistic Regression with all variables
full_model <- glm(Ploan_target ~ ., family=binomial, Ploan_trn)
summary(full_model)
full_model_coeff <- as.matrix(full_model$coefficients, 12, 1)</pre>
```

- √ glm() function: provide logistic regression model
 - Arg I: Formula, "Target ~ Input" form, period(.) for input means all variables except the target variable are used as input variables
 - Arg 2: dataset for training
- ✓ summary(): provide summarized information of the trained model
- ✓ Store the regression coefficients for further comparison

- Logistic Regression I:All variables
 - √ Insignificant variables (alpha = 0.05)
 - Age
 - Experience
 - Mortgage
 - Online

```

    GA perf <- perf eval(GA lr cm)
    return(GA perf[6])
```

- Logistic Regression 5: Genetic Algorithm
 - ✓ fit_FI() function
 - Input: chromosome (binary vector whose length is the same as the number of variables)
 - 1: use the corresponding variable in the current model
 - 0: do not use the corresponding variable in the current model
 - Example

Output: fitness function in terms of FI measure (cut-off = 0.5)

Logistic Regression 5: Genetic Algorithm

- √ ga() function: variable selected via genetic algorithm
 - Arg I: type of chromosome, if it is "binary", each gene has either 0 or I value
 - Arg 2: fitness function
 - Arg 3 & 4: number of variables and variable names
 - Arg 5 & 6 & 7: number of chromosomes, crossover rate, mutation rate
 - Arg 8 & 9: Maximum number of iterations, number of chromosomes to preserve

Logistic Regression 5: Genetic Algorithm

```
best_var_idx <- which(GA_F1@solution == 1)

# Model training based on the best variable subset
GA_trn_data <- Ploan_trn[,c(best_var_idx, 12)]
GA_tst_data <- Ploan_tst[,c(best_var_idx, 12)]
GA_model <- glm(Ploan_target ~ ., family=binomial, GA_trn_data)

summary(GA_model)
GA_model_coeff <- as.matrix(GA_model$coefficients, 12, 1)
GA_model_coeff</pre>
```

√ best_var_idx: index of best variable subset selected by GA

```
> best_var_idx
[1] 1 3 4 5 6 7 8 9 11
```
